Question 1
Correct
Mark 100.00 out of 100.00
Flag question
Edit question

You are given an $n \times 4$ integer matrix `matrix` with the following two properties:

- Each row is sorted in non-decreasing order.
- The first integer of each row is greater than the last integer of the previous row.

Given an integer `target`, return `true` if `target` is in `matrix` or `false` otherwise.

You must write a solution in $O(\log(n))$ time complexity.

Example 1:

Input: matrix = [[1,3,5,7],[10,11,16,20],[23,30,34,60]], target = 3
Output: true

Example 2:

Input: matrix = [[1,3,5,7],[10,11,16,20],[23,30,34,60]], target = 13
Output: false

For example:

Test	Result
print(searchMatrix([[1,3,5,7],[10,11,16,20],[23,30,34,60]], 3))	True
print(searchMatrix([[1,3,5,7],[10,11,16,20],[23,30,34,60]], 13))	False

Answer: (penalty regime: 0 %)

Reset answer

```
def searchMatrix(matrix, target):
    if not matrix or not matrix[0]:
        return False

    rows = len(matrix)
    cols = 4
    left, right = 0, rows * cols - 1

    while left <= right:
        mid = (left + right) // 2
        mid_val = matrix[mid // cols][mid % cols]

        if mid_val == target:
            return True
        elif mid_val < target:
            left = mid + 1
        else:
            right = mid - 1

    return False
```

Test	Expected	Got
print(searchMatrix([[1,3,5,7],[10,11,16,20],[23,30,34,60]], 3))	True	True
print(searchMatrix([[1,3,5,7],[10,11,16,20],[23,30,34,60]], 13))	False	False

Question 2
Correct
Mark 100.00 out of 100.00
Flag question
Edit question

You only receive $0, $5 and $10 as payload as the input. The program must print first 5 characters present in ST which are also present in AR.

Input Format:

The first line contains S1.
The second line contains S2.
The third line contains S3.

Output Format:

The first line contains the 5 characters present in ST which are also present in S2.

Boundary Conditions:

2 <= len <= 20
2 <= length of S1, S2 <= 1000

Example Input/Output Format 1:

Input:

abcfde
fdaecb
g

Output:

bull

Note:

In source text is common but must be printed only once.

Answer: (penalty regime: 0 %)

```
S1 = input()
S2 = input()
S3 = input()
result = ""
for ch in S1:
    if ch in S2 and ch not in result:
        result += ch
        if len(result) == 5:
            break
print(result)
```

Input	Expected	Got
abcfde fdaecb g	bull	bull

Edit question

Given an array `nums` containing `n` distinct numbers in the range `[0, n]`, return the only number in the range that is missing from the array.

Example 1:

Input: nums = [3,0,1]
Output: 2
Explanation: n = 3 since there are 3 numbers, so all numbers are in the range [0,3]. 2 is the missing number in the range since it does not appear in nums.

Example 2:

Input: nums = [9,6,4,2,3,5,7,0,1]
Output: 8
Explanation: n = 9 since there are 9 numbers, so all numbers are in the range [0,9]. 8 is the missing number in the range since it does not appear in nums.

For example:

Test	Result
print(missingNumber([3,0,1]))	2
print(missingNumber([9,6,4,2,3,5,7,0,1]))	8

Answer: (penalty regime: 0 %)

Reset answer

```
def missingNumber(nums):
    n = len(nums)
    total = n * (n + 1) // 2
    return total - sum(nums)
```

Test	Expected	Got
print(missingNumber([3,0,1]))	2	2
print(missingNumber([0,1]))	2	2
print(missingNumber([9,6,4,2,3,5,7,0,1]))	8	8

Edit question

Given an $m \times n$ binary matrix `mat`, return the distance of the nearest `0` for each cell.

The distance between two adjacent cells is `1`.

Example 1:

Input: mat = [[0,0,0],[0,1,0],[0,0,0]]
Output: [[0,0,0],[0,1,0],[0,0,0]]

Example 2:

Input: mat = [[0,0,0],[0,1,0],[1,1,1]]
Output: [[0,0,0],[0,1,0],[1,2,1]]

Constraints:

- $m == mat.length$
- $n == mat[i].length$
- $1 <= m, n <= 10^4$
- $1 <= m * n <= 10^4$
- $mat[i][j]$ is either `0` or `1`.
- There is at least one `0` in `mat`.

Note: This question is the same as 542: https://leetcode.com/problems/01-matrix/

For example:

Input	Result
3 3 0 0 0 0 1 0 0 0 0	0 0 0 0 1 0 0 0 0

Answer: (penalty regime: 0 %)

```
from collections import deque

m, n = map(int, input().split())
mat = [list(map(int, input().split())) for _ in range(m)]

dist = [[-1] * n for _ in range(m)]
q = deque()

for i in range(m):
    for j in range(n):
        if mat[i][j] == 0:
            dist[i][j] = 0
            q.append((i, j))

while q:
    x, y = q.popleft()
    for dx, dy in [(-1, 0), (1, 0), (0, -1), (0, 1)]:
        nx, ny = x + dx, y + dy
        if 0 <= nx < m and 0 <= ny < n and dist[nx][ny] == -1:
            dist[nx][ny] = dist[x][y] + 1
            q.append((nx, ny))

for row in dist:
    print(*row)
```

Input	Expected	Got
3 3 0 0 0 0 1 0 0 0 0	0 0 0 0 1 0 0 0 0	0 0 0 0 1 0 0 0 0
3 3 0 0 0 0 1 0 1 1 1	0 0 0 0 1 0 1 2 1	0 0 0 0 1 0 1 2 1

Edit question

Given an array of integers `nums` which is sorted in ascending order, and an integer `target`, write a function to search `target` in `nums`. If `target` exists, then return its index. Otherwise, return `-1`.

You must write an algorithm with $O(\log n)$ runtime complexity.

Example 1:

Input: nums = [-1,0,3,5,9,12], target = 9
Output: 4
Explanation: 9 exists in nums and its index is 4

Example 2:

Input: nums = [-1,0,3,5,9,12], target = 2
Output: -1
Explanation: 2 does not exist in nums so return -1

Constraints:

- $1 <= nums.length <= 10^4$
- $-10^4 < nums[i], target < 10^4$
- All the integers in `nums` are **unique**.
- `nums` is sorted in ascending order.

For example:

Test	Result
print(search([-1,0,3,5,9,12], 9))	4

Answer: (penalty regime: 0 %)

Reset answer

```
def search(nums, target):
    left, right = 0, len(nums) - 1

    while left <= right:
        mid = (left + right) // 2

        if nums[mid] == target:
            return mid
        elif nums[mid] < target:
            left = mid + 1
        else:
            right = mid - 1

    return -1
```

Test	Expected	Got
print(search([-1,0,3,5,9,12], 9))	4	4
print(search([-1,0,3,5,9,12], 2))	-1	-1

Edit question

An Adi company's owner is concerned and you need to determine whether two of his numbers sum to a given number K. For example, if the input is 8 and the numbers 1 and 7 are in the list, the answer is yes (or 1 and 7 multiply to make 8).

Input Format

The first line contains a single integer n, the length of the list.
The second line contains n space-separated integers, list[i].
The third line contains integer k.

Output Format

Print Yes, or No.

Sample Input

```
3
1 2 3
4
```

Sample Output

```
Yes
```

For example:

Input	Result
3 1 2 3 4	Yes
4 1 5 10 15 11	No

Answer: (penalty regime: 0 %)

```
n = int(input())
nums = list(map(int, input().split()))
k = int(input())

seen = set()
found = False
for num in nums:
    if k - num in seen:
        found = True
        break
    seen.add(num)

print("Yes" if found else "No")
```

Input	Expected	Got
3 1 2 3 4	Yes	Yes
4 1 5 10 15 11	No	No
5 4 2 9 11 6 15	Yes	Yes
3 4 2 6 11	No	No

Edit question

Balanced strings are those that have an equal quantity of 'L' and 'R' characters.
Given a balanced string s, split it in the maximum amount of balanced strings.
Return the maximum amount of split balanced strings.

Example 1:
Input:
RLRRLLRLRL
Output:
4
Explanation: s can be split into "RL", "RRLL", "RL", "RL", each substring contains same number of 'L' and 'R'.
Input:
RLLLLRRRLR
Output:
3
Explanation: s can be split into "RL", "LLLRRR", "LR", each substring contains same number of 'L' and 'R'.
Example 3:
Input:
LLLLRRRR
Output:
1
Explanation: s can be split into "LLLLRRRR".

Constraints:
1 <= s.length <= 1000
s[i] is either 'L' or 'R'.
s is a balanced string.

For example:

Test	Result
print(balancedStrings("RLRRLLRLRL"))	4
print(balancedStrings("RLLLLRRRLR"))	3

Answer: (penalty regime: 0 %)

Reset answer

```
def balancedStrings(s):
    count = 0
    balance = 0
    for ch in s:
        if ch == 'L':
            balance -= 1
        else:
            balance += 1
        if balance == 0:
            count += 1
    return count
```

Test	Expected	Got
print(balancedStrings("RLRRLLRLRL"))	4	4
print(balancedStrings("RLLLLRRRLR"))	3	3
